2

IN THE CLAIMS

1. (Currently Amended) In a multi-protocol label switching (MPLS) data network comprised of a plurality of data switches interconnected to form a plurality of data paths to a destination node, a method of routing a first message between a second and a first data switch comprised of the steps of:

establishing a downstream working path <u>for data traffic</u> that includes said first data switch and said second data switch;

establishing a downstream protection path associated with the working path;

establishing an upstream reverse notification path <u>for signal traffic separate from the protection path and associated with said working path;</u>

routing a first the first message from said second data switch to said first data switch via said upstream reverse notification path, the first message providing a fault status indication for said working path.

- 2. (Previously Presented) The data network of claim 1 wherein said upstream reverse notification path is co-incident with said working path through said network.
- 3. (Previously Presented) The method of claim 1 wherein a topology of said upstream reverse notification path can be represented by a directed acyclical graph.
- 4. (Previously Presented) The method of claim 1 wherein said data switches are asynchronous transfer mode switches that function as label switched routers.
